Signed quitting and symmetric universal priors

21 October 2026

Read the unified quitting paper

The complete exposition is now in *Quitting thresholds and reward normalization in universal intelligence*.

Sections 5–7 prove the signed expected-value result: for every real threshold there are computable agents and a suitably chosen symmetric universal reference machine violating Question 26's implication. Appendix A supplies the encoding and universal-tail budget. Sections 3–4 explain the different ultrafilter and pathwise outcomes.
